# THE $p$ -ADIC NUMBERS OF HENSEL\*

C. C. MACDUFFEE, University of Wisconsin

**1. Introduction.** One cannot blame a respectable mathematician for looking twice at the equation

$$-1 = 4 + 4 \cdot 5 + 4 \cdot 5^2 + 4 \cdot 5^3 + \dots$$

However, if we add 1 to both sides of this equation, we have

$$\begin{aligned} 0 &= 5 + 4 \cdot 5 + 4 \cdot 5^2 + 4 \cdot 5^3 + \dots \\ &= 0 + 5 \cdot 5 + 4 \cdot 5^2 + 4 \cdot 5^3 + \dots \\ &= 0 + \quad 0 + 5 \cdot 5^2 + 4 \cdot 5^3 + \dots \\ &= 0 + \quad 0 + \quad 0 + 5 \cdot 5^3 + \dots \\ &= 0 + \quad 0 + \quad 0 + \quad 0 + \dots \end{aligned}$$

with 0's as far out as we care to carry it.

It may also seem a trifle strange to write

$$2/3 = 4 + 1 \cdot 5 + 3 \cdot 5^2 + 1 \cdot 5^3 + 3 \cdot 5^4 + \dots,$$

where the coefficients beyond the first are alternately 1 and 3. Yet multiplying by 3 gives

$$\begin{aligned} 2 &= 12 + 3 \cdot 5 + 9 \cdot 5^2 + 3 \cdot 5^3 + 9 \cdot 5^4 + \dots \\ &= 2 + \quad 0 + \quad 0 + \quad 0 + \quad 0 + \dots \end{aligned}$$

Furthermore

$$\sqrt{7} = 1 + 1 \cdot 3 + 1 \cdot 3^2 + 0 \cdot 3^3 + 2 \cdot 3^4 + \dots$$

For if we square this series, retaining only terms whose exponents are  $\leq 4$ , we have

$$\begin{aligned} 7 &= 1 + 2 \cdot 3 + 3 \cdot 3^2 + 2 \cdot 3^3 + 5 \cdot 3^4 + \dots \\ &= 1 + 2 \cdot 3 + \quad 0 + \quad 0 + \quad 0 + \dots \end{aligned}$$

**2. Justification of the  $p$ -adic numbers.** No one will deny that the above examples put a heavy strain on our earlier conceptions of the terms *equality* and *convergence*. It is obvious that the statement

$$-1 = 4 + 4 \cdot 5 + 4 \cdot 5^2 + 4 \cdot 5^3 + \dots$$

is absurd if ordinary convergence is intended. The whole point to Hensel's theory is that this is not ordinary convergence, but a new type of convergence which, from the point of view of abstract algebra, is equally worthy of the name.

A relation of equality for a mathematical system  $\Sigma$  is defined as follows. Let  $a$ ,  $b$ , and  $c$  be elements of  $\Sigma$ . Then

---

\* Presented for the Slaughter Memorial Volume of the MONTHLY.

1. Either  $a = b$  or  $a \neq b$  (Determinative property).
2.  $a = a$  (Reflexive).
3. If  $a = b$ , then  $b = a$  (Symmetric).
4. If  $a = b$  and  $b = c$ , then  $a = c$  (Transitive).

These four properties of equality are all that are needed in mathematics, and consequently constitute an abstract formulation of the concept.

When Hensel\* introduced the  $p$ -adic numbers, his treatment was somewhat informal, but he had a perfectly sound feeling for what he was doing. The present vogue is to introduce the  $p$ -adic numbers by a method due to Kürschák,† similar to the well known development of the real numbers by Cauchy sequences.‡

Let  $a, b, \dots$  be rational numbers. A function  $\phi$  is called a *valuation* if

1.  $\phi(a)$  is a positive number or 0,
2.  $\phi(a) > 0$  for  $a \neq 0$ ,  $\phi(0) = 0$ ,
3.  $\phi(ab) = \phi(a) \cdot \phi(b)$ ,
4.  $\phi(a+b) \leq \phi(a) + \phi(b)$ .

From (3) with  $b = 1$ , we have  $\phi(1) = 1$ . From (3) with  $a = b = -1$ , we have  $\phi(-1) = 1$ . Then, with  $a = -1$ , we have  $\phi(-b) = \phi(b)$ .

Clearly ordinary absolute value,  $\phi(a) = |a|$ , is a valuation. Furthermore, the four properties listed above constitute an abstract formulation of the concept of absolute value in the sense that only these properties are needed for the development of the real numbers from the rational numbers by the method of regular sequences.

We recall that the ordinary integers or whole numbers  $0, \pm 1, \pm 2, \pm 3, \dots$  are called the *rational integers*, to distinguish them from algebraic integers such as  $-\frac{1}{2} - \frac{1}{2}\sqrt{-3}$  which are not rational. A *rational prime* such as  $\pm 2, \pm 3, \pm 5, \pm 7, \dots$  is a rational integer neither 0 nor  $\pm 1$  such that, if it is resolved into a product of two rational integral factors, one of the factors must be 1 or  $-1$ . Two integers are *relatively prime*, or *prime to each other*, if their only common divisors are  $\pm 1$ .

Let  $p$  be a fixed rational prime. Every rational number  $a \neq 0$  is uniquely expressible in the form

$$a = (r/s)p^n, \quad s > 0,$$

where  $r$  and  $s$  are rational integers prime to each other and to  $p$ , and  $n$  is a rational integer. We define

$$\phi(a) = p^{-n}, \quad a \neq 0, \quad \phi(0) = 0.$$

*The function  $\phi(a)$  is a valuation for the rational field.*

Properties (1) and (2) are evident. If

\* K. Hensel, *Theorie der algebraischen Zahlen*, Teubner, 1908.

† J. Kürschák, *Journal für die reine und angewandte Mathematik*, vol. 142, 1913, pp. 211–253.

‡ See B. L. van der Waerden, *Moderne Algebra*, 2nd ed. I, Springer 1937, p. 221.

$$a = (r_1/s_1)p^m, \quad b = (r_2/s_2)p^n,$$

where  $r_1, s_1, r_2$ , and  $s_2$  are prime to  $p$ , then

$$ab = (r_1r_2/s_1s_2)p^{m+n},$$

where  $r_1r_2$  and  $s_1s_2$  are prime to  $p$ . Hence

$$\phi(ab) = p^{-m-n} = \phi(a) \cdot \phi(b).$$

Without loss of generality assume that  $m \leq n$ . Then

$$a + b = \frac{r_1s_2 + r_2s_1p^{n-m}}{s_1s_2} p^m,$$

where  $s_1s_2$  is prime to  $p$ , so that

$$\phi(a + b) \leq p^{-m} = \phi(a),$$

$$\phi(a + b) \leq \phi(a) + \phi(b).$$

Let  $p$  be a fixed prime, and let  $\phi$  be defined relative to  $p$ . A sequence

$$\{a_i\} = (a_1, a_2, a_3, \dots, a_i, \dots)$$

of rational numbers is called *regular* if for every positive rational number  $\epsilon$  there is a positive integer  $n_\epsilon$  such that

$$\phi(a_i - a_j) < \epsilon \quad i, j > n_\epsilon.$$

Denote by  $\Omega_p$  the set of all regular sequences  $\{a_i\}$ . Two such sequences are defined to be *equal* if, for every  $\epsilon$ , there is an  $n_\epsilon$  such that

$$\phi(a_i - b_i) < \epsilon \quad i > n_\epsilon.$$

*Equality as defined above is determinative, reflexive, symmetric, and transitive.*

The determinative property is evident. The reflexive property follows from the definition of regularity. Symmetry follows from the fact that  $\phi(-a) = \phi(a)$ . Transitivity follows from the "triangle property"  $\phi(a+b) \leq \phi(a) + \phi(b)$ .

The theory now proceeds as in the usual treatment of real numbers as regular sequences. We define

$$\{a_i\} + \{b_i\} = \{a_i + b_i\}, \quad \{a_i\} \cdot \{b_i\} = \{a_ib_i\}.$$

The sum and product of regular sequences are regular. The set  $\Omega_p$  of all regular sequences, with equality, addition, and multiplication as we have defined them, is a field of characteristic zero—that is, it is a field which contains a subfield isomorphic with the rational field. Indeed, two fields  $\Omega_p$  and  $\Omega_q$  where  $p$  and  $q$  are distinct primes are non isomorphic so that we obtain infinitely many essentially different fields, each, of course, different from the real field. But like the real field every  $\Omega_p$  is perfect—that is, incapable of further extension by means of regular sequences based on a valuation which extends the valuation by which  $\Omega_p$  was defined.

It is one of the standard procedures in analysis to show that every real number can be represented as an infinite decimal—that is, a series of the type

$$a_{-\nu} \left( \frac{1}{10} \right)^{-\nu} + \cdots + a_0 + a_1 \left( \frac{1}{10} \right) + a_2 \left( \frac{1}{10} \right)^2 + \cdots$$

or the negative of such a series, with  $0 \leq a_i < 10$ . This process can be carried over intact to the  $p$ -adic fields. It may be proved that every regular  $p$ -adic sequence is equal in the  $p$ -adic sense to a sequence

$$p^{-\nu} \{d_i\}, \quad \{d_i\} = (a_0, a_0 + a_1 p, a_0 + a_1 p + a_2 p^2, \cdots), \quad 0 \leq a_i < p.$$

That is, every  $p$ -adic number may be represented by a power series

$$a_{-\nu} p^{-\nu} + \cdots + a_0 + a_1 p + a_2 p^2 + \cdots, \quad 0 \leq a_i < p.$$

Just as the infinite decimal is automatically convergent in the Cauchy sense, so is the above series automatically convergent in the  $p$ -adic sense.

It is to be emphasized that for every rational prime  $p$  there is a field  $\Omega_p$  quite comparable with the field of real numbers, but not isomorphic with it, nor with any other  $\Omega_p$ . The field  $\Omega_2$  is the field of all *diadic* numbers,  $\Omega_3$  of all *triadic* numbers,  $\Omega_5$  of all *pentadic* numbers, etc. Once the field has been selected, all calculations remain in this field. We cannot add or multiply a triadic number and a pentadic number, for instance.

**3. Solution of equations.** Now that we understand the meaning of a statement such as

$$\sqrt{7} = 1 + 1 \cdot 3 + 1 \cdot 3^2 + 0 \cdot 3^3 + 2 \cdot 3^4 + \cdots,$$

it remains to show how any desired number of terms of the expansion can be derived.

First we note that every  $p$ -adic number

$$a_{-\nu} p^{-\nu} + \cdots + a_0 + a_1 p + a_2 p^2 + \cdots, \quad 0 \leq a_i < p,$$

is the sum of a rational number

$$a_{-\nu} p^{-\nu} + \cdots + a_{-1} p^{-1}$$

and a number

$$a_0 + a_1 p + a_2 p^2 + \cdots$$

having no negative exponents, which is called an *integral  $p$ -adic number*, or a  *$p$ -adic integer*.

Two  $p$ -adic integers

$$\alpha = a_0 + a_1 p + a_2 p^2 + \cdots, \quad 0 \leq a_i < p,$$

$$\beta = b_0 + b_1 p + b_2 p^2 + \cdots, \quad 0 \leq b_i < p,$$

are equal in the  $p$ -adic sense, according to the definition of §2, if for every  $\epsilon > 0$

$$f(\alpha_{n-1}) \equiv 0 \pmod{p^n},$$

. . . . .

holds.

The problem is now reduced to a familiar one in congruences. Whether  $f(x) \equiv 0 \pmod{p}$  has a solution or not is usually best determined by trial. If there is a solution, there is a solution  $\alpha_0$ ,  $0 \leq \alpha_0 < p$ .

Now there is a well known step-by-step process for finding a solution  $\pmod{p^{n+1}}$  when a solution  $\pmod{p^n}$  is known.\* Suppose that

$$\alpha_{n-1} = a_0 + a_1p + a_2p^2 + \cdots + a_{n-1}p^{n-1}, \quad f(\alpha_{n-1}) \equiv 0 \pmod{p^n}.$$

We wish to find  $a_n$  so that

$$\alpha_n = \alpha_{n-1} + a_np^n, \quad f(\alpha_n) \equiv 0 \pmod{p^{n+1}}.$$

By the binomial theorem,

$$\begin{aligned} f(\alpha_n) &= f(\alpha_{n-1}) + a_nf'(\alpha_{n-1})p^n + \cdots \\ &\equiv f(\alpha_{n-1}) + a_nf'(\alpha_{n-1})p^n \pmod{p^{n+1}}, \end{aligned}$$

where  $f'$  denotes the derivative. Since  $f(\alpha_{n-1}) \equiv 0 \pmod{p^n}$ , there exists an integer  $h_{n-1}$  such that

$$f(\alpha_{n-1}) \equiv h_{n-1}p^n \pmod{p^{n+1}}, \quad 0 \leq h_{n-1} < p.$$

Hence  $a_n$  can be determined from the congruence

$$a_nf'(\alpha_{n-1})p^n + h_{n-1}p^n \equiv 0 \pmod{p^{n+1}},$$

which is equivalent to the congruence

$$(1) \quad a_nf'(\alpha_{n-1}) + h_{n-1} \equiv 0 \pmod{p}.$$

Clearly  $a_n$  will exist unless  $f'(\alpha_{n-1}) \equiv 0$ ,  $h_{n-1} \not\equiv 0 \pmod{p}$ . If it exists, it can be chosen in the interval  $0 \leq a_n < p$ .

In order that

$$x^2 \equiv 7$$

be solvable in triadic numbers, it is first necessary that 7 be a quadratic residue† modulo 3. This condition is met, for both 1 and 2 are solutions of  $x^2 \equiv 7 \pmod{3}$ . Let us take the first solution. Then  $\alpha_0 = a_0 = 1$ .

$$\begin{aligned} f(x) &= x^2 - 7, & f(\alpha_0) &= -6 \equiv 3 \pmod{9}, & h_0 &\equiv 1 \pmod{3}, \\ f'(x) &= 2x, & f'(\alpha_0) &\equiv 2 \pmod{3}. \end{aligned}$$

Then (1) becomes

\* L. E. Dickson, Introduction to the theory of numbers, University of Chicago Press, 1929, p. 16, ex. 4.

† Dickson, *l.c.*, p. 30.

$$2a_1 + 1 \equiv 0 \pmod{3},$$

which has the solution  $a_1 = 1$ . Thus  $\alpha_1 = 1 + 1 \cdot 3 = 4$  is a solution of  $x^2 \equiv 7 \pmod{9}$ .

The second step gives  $\alpha_1 = 4$ ,

$$\begin{aligned} f(\alpha_1) &= 9, & h_1 &= 1, & f'(\alpha_1) &= 8 \equiv 2 \pmod{3}, \\ 2a_2 + 1 &\equiv 0 \pmod{3}, & a_2 &= 1, & \alpha_2 &= 1 + 1 \cdot 3 + 1 \cdot 3^2. \end{aligned}$$

Two more steps give

$$\alpha_4 = 1 + 1 \cdot 3 + 1 \cdot 3^2 + 0 \cdot 3^3 + 2 \cdot 3^4,$$

which was checked in §1.

The other value of  $a_0$ , namely 2, is the first term of another triadic solution,

$$\beta = 2 + 1 \cdot 3 + 1 \cdot 3^2 + 2 \cdot 3^3 + 0 \cdot 3^4 + \dots$$

There are no other triadic solutions of  $x^2 = 7$ .

The equation

$$x^2 + x + 1 = 0,$$

whose roots in the complex field are not real has no solution in pentadic numbers, since

$$x^2 + x + 1 \equiv 0 \pmod{5}$$

has no solution. However, it has two heptadic solutions,

$$\begin{aligned} \alpha &= 2 + 4 \cdot 7 + 6 \cdot 7^2 + \dots, \\ \beta &= 4 + 2 \cdot 7 + 0 \cdot 7^2 + \dots \end{aligned}$$

with the usual relations  $\alpha^2 = \beta$  and  $\beta^2 = \alpha$ . It is incorrect to think of these solutions as being complex numbers—they belong to the field  $\Omega_7$ .

So far we have looked only for integral  $p$ -adic solutions of  $f(x) = 0$ . But if the leading coefficient of  $f(x)$  is divisible by  $p$  while not all of the other coefficients are divisible by  $p$ ,  $f(x) = 0$  may have a  $p$ -adic solution which is not integral. But this situation involves no difficulty, for a simple transformation reduces this case to the preceding.

Consider the equation

$$9x^2 = 7, \quad \Omega_3.$$

This has no integral triadic solution, since

$$9x^2 - 7 \equiv 0 \pmod{3}$$

has no solution. But a transformation  $3x = y$  yields an equation  $y^2 = 7$  which we have solved in  $\Omega_3$ . Then the given equation has as solutions the fractional triadic numbers

$$\begin{aligned} \alpha &= 3^{-1} + 1 + 1 \cdot 3 + 0 \cdot 3^2 + 2 \cdot 3^3 + \dots, \\ \beta &= 2 \cdot 3^{-1} + 1 + 1 \cdot 3 + 2 \cdot 3^2 + 0 \cdot 3^3 + \dots \end{aligned}$$

**4. Rational numbers in  $\Omega_p$ .** The close analogy of the  $p$ -adic series with infinite decimals is well exemplified in the behavior of the rational numbers. A rational number  $r/s$  with  $r$  prime to  $s$  can be expressed as a finite decimal if and only if every prime factor of  $s$  is 2 or 5. A positive rational number  $r/s$  with  $r$  prime to  $s$  can be expressed by a finite  $p$ -adic series if and only if  $s$  is a power of  $p$ .

A decimal is finite or periodic if and only if it is equal to a rational number. Analogously

*A  $p$ -adic series is finite or periodic if and only if it is equal to a rational number.*

It will be sufficiently general to consider the series

$$\alpha = A + p^k B + p^{k+l} B + p^{k+2l} B + \cdots,$$

where

$$\begin{aligned} A &= a_0 + a_1 p + \cdots + a_{k-1} p^{k-1}, & 0 \leq a_i < p, \\ B &= b_0 + b_1 p + \cdots + b_{l-1} p^{l-1}, & 0 \leq b_i < p. \end{aligned}$$

We shall call  $B$  the *period* of  $\alpha$ . Then

$$\alpha - A = p^k B + p^l [p^k B + p^{k+l} B + \cdots] = p^k B + p^l [\alpha - A];$$

that is,

$$\alpha = A + \frac{p^k B}{1 - p^l},$$

which is clearly rational.

To prove the converse, first suppose that  $\alpha = r/s$  is a negative proper rational fraction,  $r$  prime to  $s$ ,  $s$  prime to  $p$  and positive. There exist positive integers  $l$  such that

$$p^l \equiv 1 \pmod{s}$$

by Euler's theorem. Let  $l$  be the smallest such integer—that is,  $l$  is the exponent to which  $p$  belongs\* modulo  $s$ . Let

$$1 - p^l = ms, \quad m < 0, \quad mr > 0.$$

Then

$$\alpha = r/s = mr/(1 - p^l).$$

Since  $\alpha$  is proper,  $mr$  is expressible in the form

$$mr = B = b_0 + b_1 p + \cdots + b_{l-1} p^{l-1}, \quad 0 \leq b_i < p.$$

Then

$$\alpha = B + p^l B + p^{2l} B + \cdots$$

is periodic.

---

\* Dickson, *l.c.*, p. 16.

If  $\alpha$  is positive, it can be written as the sum of a polynomial in  $p$  and a negative proper fraction. The development of  $-\alpha$  can be obtained by subtracting the development of  $\alpha$  from

$$0 = p \cdot 1 + (p-1) \cdot p + (p-1) \cdot p^2 + (p-1) \cdot p^3 + \cdots$$

Neither of these operations will destroy the eventual periodicity of the series.

The methods of this paragraph are quicker and more effective for rational numbers than the more general method of §3.

**5. Generalizations.** The ideas which were disclosed in the development of the  $p$ -adic numbers have inspired much modern research. Hensel\* himself extended the theory far beyond the simple  $p$ -adic fields: to  $g$ -adic rings where  $g$  is not a prime, to  $p$ -adic extensions of algebraic fields, and to functions over such fields and rings. The concepts of valuation and  $p$ -adic extension are of great importance in the modern theory of linear algebras,† and their ramifications are still being explored.

## A NOTE ON THE USE OF THE LAPLACE TRANSFORMATION

H. P. THIELMAN, College of St. Thomas

In recent years a great deal of work has centered around the Laplace transform of a function  $F(t)$ .‡ In this note we shall prove an elementary theorem concerning such a transform, and show how it may be used in evaluating some definite integrals.

By definition the Laplace transform of  $F(t)$  is the function  $f(\alpha)$  given by the formula

$$f(\alpha) = \int_0^{\infty} e^{-\alpha t} F(t) dt.$$

We shall first prove the following:

**THEOREM:** *If  $f(\alpha)$  is the Laplace transform of  $F(t)$ , then*

$$\int_0^{\infty} f(\alpha) d\alpha = \int_0^{\infty} \frac{F(t)}{t} dt,$$

*provided these integrals exist.*

The proof of this theorem goes as follows: From the hypothesis that the second one of the last two integrals exists, it follows that the integral
